

Fresh leadership 8-Ks did not reward put sellers: a pre-registered null that replicated in sign

Gator Quant Hacks 2026 · Systematic Trading track · Massive “Trade the 8-K” bonus · Team LuisGandora & jack-uf · Repo: github.com/LuisGandora/GatorQuantHacks_2026 · Every number in this note is printed by `gator-quant-hacks-8k-options-challenge.ipynb` when run top to bottom; `run(start_date, end_date)` reproduces them.

1 • Summary

Claim tested (pre-registered): after a *fresh* leadership-change 8-K (the filing is the first public disclosure), the option chain over-prices the coming move, so a cash-secured put sold at the post-filing close beats ordinary days for the same stocks; after a *stale* one (filed days after a press release) it does not.

Result: rejected, in the opposite direction, and the rejection replicated in sign. Net of costs, the fresh-filing put seller did -1.16% worse than ordinary days in-sample ($n = 55$) and -0.71% out-of-sample ($n = 25$), averaged over $h = 21, 42$ and expiry. The fresh–stale gap is negative in both windows; its 95% interval excludes zero out-of-sample only. As a portfolio the strategy lost money in both windows at $1\times$ and $2\times$ costs (Sharpe -0.57 in-sample, -1.31 out-of-sample). The actionable finding for a PM is a “**don’t**”: do not sell downside protection after fresh governance shocks.

Everything else we tested is null, including our first hypothesis (JEV, §2), a variance-premium map over 18 categories and 12 conditional hypotheses; §5.4 counts every variant.

2 • Economic hypothesis (as pre-registered, word for word)

H1 (first, JEV).

“Within the same 8-K disclosure category, filings that JEV scores as higher in semantic event intensity, confidence, and judgment stability will be followed by larger realized stock moves relative to the pre-event options-implied move than lower-scoring filings. We expect this relationship to be strongest when JEV identifies a disclosure as both economically significant and non-routine, indicating that the coarse 8-K category alone does not fully capture the information relevant to options-market pricing.”

H2 (freshness; the headline test), written after H1 failed, before any H2 P&L (tag freeze-v2):

“We expect leadership-change 8-Ks at the top 100 to over-price the move only when the 8-K is the first public disclosure. Holders who are surprised by a governance shock buy protection right after it and over-pay. When the 8-K is filed days after a press release, the chain has already re-priced, and there’s no premium left. If true, the cash-secured put entered at the post-filing close beats ordinary days on fresh filings but not on stale ones. It fails if fresh and stale filings earn the same.”

Who is on the other side. The thesis names surprised holders buying protection after a governance shock as the counterparty who over-pays; we sell them the put. Their identity is not observed in the data. **Why it is not obvious:** an 8-K must be filed within four business days, so the same Massive category is sometimes news and sometimes a recap. Freshness is measured from the EDGAR header, not from the category, which is exactly the information the coarse tag hides. **Failure conditions (pre-registered):** fresh vs ordinary days ≤ 0 , or fresh – stale ≤ 0 , or no decline in edge with filing lag.

3 • Data and universe

- **Universe:** the starter notebook’s static list of the 100 largest US companies (September 2026), applied to every window (survivorship caveat, §8).
- **Events:** Massive Filings & Disclosures 8-K tags `ceo_appointment`, `ceo_departure`, `cfo_appointment`, `cfo_departure`, `executive_officer_appointment`; one event per ticker and filing session. Found: in-sample 62 fresh / 108 stale; out-of-sample 27 fresh / 42 stale (fewer are priced: some have no tradeable chain).
- **Freshness:** lag = trading sessions from the 8-K’s *CONFORMED PERIOD OF REPORT* (EDGAR submission header, “date of earliest event reported”) to the filing session. Fresh if lag ≤ 1 , stale otherwise.

- **Options:** Massive options contracts and daily aggregates (unadjusted); spot from the chain by put-call parity (no stock feed).
- **Windows:** in-sample 2024-01-01 to 2025-12-31; out-of-sample 2026-01-01 to 2026-08-31, looked at once; judges' sealed window 2023-06-01 to 2023-08-31 (replaces the track's 20% holdout under the Massive rule). A dated correction in runs/PREREG.md fixes windows it first misstated; the windows run are the notebook defaults.
- **Data handling:** filings accepted after 16:00 ET (EDGAR acceptance timestamp) move to the next session; a leg's mark must be at most 3 sessions old or the session is missing (never filled from later data); non-standard post-split contracts are dropped.

4 • Methodology

- **Trade:** sell a cash-secured put 5% below spot, 3-6 month expiry, at the close of the filing session (after the after-hours shift, so no lookahead). Marked at every fixed horizon $h = 1, 2, 3, 5, 10, 21, 42, 63$ sessions and at expiry.
- **Control:** ordinary days for the same tickers (the notebook's placebo: 120 random sessions per window, drawn in proportion to each ticker's events, at least 30 days from any event), priced and traded identically.
- **Statistic:** mean P&L per \$1 of spot, events minus ordinary days, with a 95% bootstrap interval (2,000 draws). The pre-registered **edge** averages $h = 21, 42$ and expiry.
- **Costs:** no quotes exist in the data, so each side costs 5% of the put's premium (the starter's haircut), charged on events and ordinary days alike; **2×** doubles it. Tables are net unless marked gross.
- **Discipline:** rules frozen in git tags before P&L; every test appended to runs/ledger.jsonl; the harness refuses a second out-of-sample look. Multi-category tests use Benjamini-Hochberg ($q = 0.10$); only passers earn an out-of-sample look.

5 • Results

5.1 Headline: H2, every fixed horizon, both windows, net of costs

	In-sample 2024–25			Out-of-sample 2026

	In-sample 2024–25		Out-of-sample 2026			
Horizon	Fresh – ord.	Stale – ord.	Fresh – stale	Fresh – ord.	Stale – ord.	Fresh – stale
n (events / control)	55 / 105	95 / 105	55 / 95	25 / 102	40 / 102	25 / 40

Difference in mean P&L per \$1 of spot (%), net of a 5%-per-side haircut; 95% bootstrap interval below each value. n is the number of events at the edge horizons (fresh, stale, ordinary days).

Fresh vs ordinary days is negative at the edge horizons in both windows: -1.16% net in-sample (gross -1.19%) and -0.71% out-of-sample (gross -0.70%). In-sample the interval excludes zero at expiry; out-of-sample it includes zero everywhere. **Fresh – stale** (the pre-registered primary test) is -0.98% in-sample (not significant) and -2.74% out-of-sample, excluding zero at 2 of 3 edge horizons. Under the pre-registered gate (significant in-sample first) this is *not* a finding, only a consistent sign. **Stale vs ordinary days** flips from -0.18% to $+2.04\%$: unstable, not a finding. Early horizons ($h \leq 10$) are near zero in both windows, so the damage happens over weeks, not on the filing day. Gross versions of this table are in Appendix A1; costs move each edge by a few basis points because both arms pay them.

5.2 Portfolio: one put per fresh event on 1/10 of capital, held 21 sessions

Window · costs	n	Ann. return	Ann. vol	Sharpe	Max DD	Skew	Worst month	Turnover /yr	Worst event	Max open
In-sample · 1x	55	-1.18%	2.06%	-0.57	-4.56%	-2.26	-1.51%	2.72×	-16.5%	7
In-sample · 2x	55	-2.01%	2.08%	-0.97	-5.07%	-2.30	-1.62%	2.72×	-16.9%	7
Out-of-sample · 1x	25	-2.98%	2.27%	-1.31	-2.55%	-1.89	-1.11%	3.41×	-10.1%	8
Out-of-sample · 2x	25	-4.55%	2.30%	-1.98	-3.51%	-1.84	-1.27%	3.41×	-11.2%	8

Daily returns on capital; costs are half on entry and half on exit; 2× doubles the haircut. Worst event is per \$1 of notional (1/10 of capital).

Equity curve (same rule and code, harness.daily_returns): in-sample left, out-of-sample right, 1× and 2× costs.

5.3 Robustness: does it survive its neighbours, years and the simple explanation?

Neighbours. Over the 18-cell grid of expiry bucket (1m, 2m, 3-6m) × OTM (3%, 5%, 10%) × entry (pre, post), fresh vs ordinary days is below zero in **18 of 18 cells in-sample and 18 of 18 out-of-sample**: a plateau, not a tuned peak (gross; Appendix A2). **Years.** Gross edge 2024 -0.70% ($n = 27$), 2025 -1.61% ($n = 32$), 2026 -0.70% ($n = 27$); no single year carries it. **The simple explanation.** Two things hurt the put seller in both windows: fresh-event stocks fell more than on ordinary days (own-stock move edge -1.32% in-sample, -1.36% out-of-sample), and they moved more than the chain priced (median $|\text{realized}| \div \text{implied}$ 1.08 vs 0.75 on ordinary days in-sample; 0.82 vs 0.65 out-of-sample; exploratory). With no index data we cannot rule out that part of the direction effect is market beta.

5.4 Everything else we tried, and the variant count

Test	Label	Result (net of costs unless noted)	Verdict
H2 freshness (F1): 3 comparisons, §5.1	pre-reg.	fresh vs ordinary days negative in both windows	rejected; sign replicated
H1 JEV, leadership pairings scored by JEV (5 strategy tests)	pre-reg.	Gross. Cash-secured put: P-leadership -0.53% ($n = 150$); CEO change -1.01% , without its best 3 events $+0.08\%$; CFO/exec -0.58% . Covered call: -1.78% , -1.10%	null / fragile
H1 JEV judgment stability (jack-uf), cfo_appointment, 9 horizons $\times$ 3 score cutoffs	pre-reg.	stability coefficient's 95% CI includes 0 in all 27 cells	null
Blinded information novelty (jack-uf), 9 horizons $\times$ earnings in/out	pre-reg.	horizon gate passed in 0 of 18 cells	null
Good-news long call; earnings put and covered call	pre-reg.	long call -0.15% ($n = 103$); earnings put $+0.39\%$, covered call $+0.83\%$ in-sample (gross)	earnings passed in-sample, failed its one out-of-sample look*
Variance-premium map: 18 categories, $\log(\text{realized} \div \text{implied})$, events – ordinary days	pre-reg.	BH $q = 0.10$: 0 of 18 pass; smallest p 0.182 (bylaw amendment). Outside leadership, fresh – stale $+0.003$ [-0.102 , $+0.102$], p 0.999, n 666 / 547	null map; freshness does not generalize
12 conditional hypotheses (filing-day move, term structure, skew, volume, Jev tone, bundling, resolution), 1m options	pre-reg.	10 ran, 2 too few events; BH $q = 0.10$: 0 of 10 pass; smallest p 0.059 (H12 resolution events, edge -0.88% [-1.63% , $+0.03\%$])	null
Move-ratio diagnostic; 18-cell sensitivity grid; portfolio; by-year; starter CFO example; KO sample	explor.	§5.2–5.3, notebook sections 1–11	descriptive only

pre-reg. = pre-registered; explor. = exploratory. *Its out-of-sample result is in `runs/ledger.jsonl` and is not re-printed by the notebook. jack-uf's branch also records 29 earlier experiment decisions (notebook output B3), and none reports a candidate edge.

Variant count. Pre-registered tested cells printed by the notebook: 3 (F1) + 8 (earlier pairings) + 19 (map + its freshness test) + 10 (conditional hypotheses) + 27 (JEV stability) + 18 (novelty) = **85**, plus 36 exploratory sensitivity cells. Out-of-sample looks taken: three, each once (F1, earnings, map freshness test). At this count a few starred horizons are expected by chance. That is why we report only the result that held its sign out-of-sample, and why we call it a “don't”, not an edge.

6 • Risk management

Sizing: 1/10 of capital per event, cash-secured (collateral = strike $\times$ 100), at most 10 open; the backtest peaked at 7 open in-sample and 8 out-of-sample, so it never ran uncollateralized. **Measured tail:** worst single event -16.5% per \$1 notional in-sample (-10.1% out-of-sample), worst month -1.51% , max drawdown -4.56% ; skew -2.26 is the short-volatility tail the track warns about. **Correlation:** a short put is long the stock, so a market-wide sell-off hits every open position at once; with up to 8 concurrent positions that is the main risk, and without index data we could not hedge or measure it. **Assignment:** covered by the collateral; early assignment and dividends are not modelled. **Kill rule for the original trade:** do not run it after fresh leadership 8-Ks. If a desk wanted to act on the evidence, the mirror trade (buying the put) is the one the data point to. That is an untested prediction, and it would carry the opposite risk: steady premium bleed on ordinary days.

7 • Liquidity and capacity

Capacity is measured from the sold put's own traded volume over the 10 calendar days before the pre-event session. The median is 29 contracts per session in-sample (18 out-of-sample); 2% of in-sample events had no volume at all. At 1% of that volume one position carries about \$5k of notional (median; \$2k at the 25th percentile), and at 10% about \$50k (\$19k). Out-of-sample: \$4k and \$39k. With at most 10 positions open, 10% participation caps the book near ten times the per-position figure, roughly half a million dollars. **Costs in bps:** the 5%-of-premium haircut is a median 13 bps of notional per side in-sample (interquartile 10–18) and 18 bps out-of-sample (15–26). The 5%-OTM, 3-6-month puts on these names are thin. **This is a research finding about pricing, not a scalable book.**

8 • Limitations, and what would break the finding

1. **Survivorship in the universe.** The top-100 list is from September 2026 and is applied back to 2024. It changes which events are included, not how each is priced. We cannot size the effect without point-in-time membership.
2. **Freshness is approximate.** The period of report is when the event happened, which can precede the public announcement. That mixes the arms and can hide a difference but not create one.
3. **Costs are assumed,** not measured from quotes; the $2\times$ column bounds the error. The trade loses before costs, so costs cannot rescue it.
4. **No market index.** A short put is long the stock, and we cannot separate the stocks' own moves from market beta. Part of the loss may be beta.
5. **Small samples.** Out-of-sample has 25 fresh events: the sign replicated, significance on fresh vs ordinary days did not.
6. **The “under-priced” reading is post hoc.** It was written after both windows were seen, and only the sealed window can test it.

What would break it. (a) In the sealed window, fresh vs ordinary days turns positive. (b) A market-index control removes the loss, so it was beta, not the filings. (c) Point-in-time membership changes the sign. (d) Dropping a handful of extreme events flips it.

Sealed-window predictions (committed in runs/PREREG.md before the judges' window): fresh vs ordinary days is negative; fresh – stale is negative; with roughly three months of data both intervals include zero, so **the sign is the prediction, not significance**. If the sign flips, we predicted the fragility: the out-of-sample fresh vs ordinary days interval already includes zero.

Appendix (outside the five-page limit)

A3 · Variance-premium map, in-sample (events – ordinary days, mean log move ratio)

Category	n	diff	95% CI	p	BH pass
debt issuance	132	-0.070	[-0.227, +0.086]	0.383	False
executive compensation change	137	+0.038	[-0.109, +0.182]	0.572	False
annual meeting results	137	-0.021	[-0.194, +0.224]	0.875	False
investor presentation	137	+0.042	[-0.162, +0.246]	0.686	False
underwriting agreement	133	-0.084	[-0.223, +0.036]	0.188	False
executive officer departure	115	-0.008	[-0.175, +0.154]	0.906	False
quarterly earnings	117	-0.027	[-0.276, +0.197]	0.855	False
shareholder proposal outcome	112	-0.022	[-0.178, +0.201]	0.869	False
executive officer appointment	89	+0.090	[-0.097, +0.276]	0.334	False
director departure	91	+0.049	[-0.129, +0.236]	0.605	False
director appointment	88	+0.108	[-0.055, +0.271]	0.204	False
dividend declaration	74	-0.027	[-0.240, +0.232]	0.791	False
credit facility	56	+0.122	[-0.108, +0.338]	0.312	False
guidance issuance or update	52	+0.042	[-0.236, +0.292]	0.769	False
business update	49	+0.056	[-0.166, +0.266]	0.629	False
bylaw amendment	43	-0.179	[-0.459, +0.089]	0.182	False
guarantee or letter of credit	32	+0.157	[-0.177, +0.437]	0.332	False
debt retirement	35	-0.147	[-0.461, +0.139]	0.307	False

A4 · Twelve conditional hypotheses, in-sample (edge vs ordinary days, mean of h = 21, 42, expiry; month-cluster CI)

Hypothesis	n sel / pool	Status	Edge	95% CI	p	Own net 2×	BH
H01 drift after drop	334 / 1150	OK	+0.16%	[−1.32%, +1.60%]	0.836	+0.74%	False
H02 reversal after drop	365 / 1150	OK	+0.18%	[−0.53%, +0.82%]	0.618	+0.28%	False
H03 inverted term	307 / 1102	OK	−0.40%	[−2.03%, +1.21%]	0.620	+0.97%	False
H04 rich put skew	351 / 1110	OK	−0.01%	[−0.69%, +0.60%]	0.983	+0.20%	False
H05 sticky vol	299 / 1130	OK	+0.15%	[−1.31%, +1.60%]	0.804	+0.70%	False
H06 attention calls	328 / 1162	OK	−0.03%	[−1.54%, +1.36%]	0.965	+1.43%	False
H07 prefiling put volume	329 / 1162	OK	−0.37%	[−1.84%, +1.16%]	0.640	+0.32%	False
H08 negative tone	19 / 1289	OK	−2.35%	[−5.93%, +1.42%]	0.232	−1.47%	False
H09 outside successor	12 / 47	TOO FEW (<15 selected)					False
H10 bundled filing	112 / 1289	OK	−1.25%	[−3.04%, +0.57%]	0.175	−0.32%	False
H11 dividend raise	8 / 76	TOO FEW (<15 selected)					False
H12 resolution events	49 / 57	OK	−0.88%	[−1.63%, +0.03%]	0.059	−0.34%	False

These are the notebook's run(STUDY_START, STUDY_END) numbers. They differ from runs/hyp/RESULTS.md because run() draws its ordinary-day pool for the window it is given. Neither version passes BH.

A5 · What the notebook does not print

- The pre-registered lag-bucket test (edge by filing lag) and F1's drop-the-best-3 check are in runs/ledger.jsonl only.
- Out-of-sample results for the earnings pairing and the map's freshness test are in the ledger only. The map and hypotheses had no BH passers, so they earned no out-of-sample look.
- The starter's own out-of-sample cells are gated by jack-uf's RUN_OOS = False; the F1 out-of-sample numbers come from the F1 findings cell.
